CIRCUIT DESCRIPTION

INTRODUCTION

The TS-530 is a single conversion transceiver with an intermediate frequency of 8.83 MHz.

In transmission, an SSB signal generated at 8.83 MHz is mixed with the PLL local oscillator output to produce the final transmission frequency. The circuitry is hybrid with vacuum tubes used only in the driver (12BY7A) and final-stage power amplifier (6146B's).

The PLL circuit generates a heterodyne frequency for each band and a counter reference signal from a single crystal oscillator.

The TS-530 incorporates an IF SHIFT circuit, VOX (also used for CW semi-break-in), side tone circuit, speech processor, noise blanker, XTAL calibrator, and etc.

RECEIVER CIRCUIT

The signal coming from the antenna is routed through a step-up antenna coil via an RF ATT switch and IF trap. MOS FET Q1,3SK73 amplifies this signal. Approximately 9 dB of negative feedback is applied to the RF amplifier to reduce noise and expanded dynamic range. The signal passes through buffer amplifier Q2, 2SK125 and is mixed with the PLL VCO output by a balanced mixer (Q3,Q4 : 2SK125). The DOUBLE SIDE-BAND signal is now converted to the intermediate frequency, 8.83 MHz.

Entering the IF unit, this signal is amplified by Q1(2SK125), passes through ceramic filter CF1 and the NB gating circuit, and is applied to the crystal filter whose center frequency is 8.83 MHz.

The SINGLE SIDE-BAND signal leaving the crystal filter is amplified by Q2~Q4(3SK73) and is then demodulated to an audio signal by the product detector consisting of D16~D19 (1N60 x4).

In the AF unit, the audio signal is amplified by Q2(2SC2240) passes through the AF GAIN control, and after being amplified by the power amplifier Q6 (MB3712), drives the speaker.

TRANSMITTER CIRCUIT

Audio input picked up by the microphone comes to the IF unit and is amplified by Q11, 12, 15 and 16. The input circuit adapts to any microphone impedance of from 500 ohms to 50 kohms. This amplified signal is converted into a DSB signal by the balanced modulator D27~D30 (1N60 x4), passes through buffer amplifier Q18 (2SK19) and an 8.83 MHz crystal filter, and the output appears as a SSB signal. The SSB signal is amplified by Q2 (3SK73) and is applied to the transmitter mixer in the RF unit. The transmitter mixer is a double balanced mixer consisting of Q6 and Q7 (3SK73), which mixes the SSB signal with the PLL VCO output to generate the final transmission frequency. The signal is then amplified by the driver (V1 : 12BY7A) and then by the final power amplifier (two 6146B's) and is applied to the antenna via a π -matching network.

PLL CIRCUIT

The PLL signal is synthesized from the VFO, CAR and VCO outputs. The TS-530S employs a programmable divider in the PLL to synthesize the heterodyne frequency from the standard reference oscillator frequency. This simplifies the PLL circuit by eliminating the need for a separate HET XTAL for each band.

Frequency organization of the PLL circuit is shown in **Fig. 1**, the circuit diagram in **Fig. 2**, and frequency organization in other circuits is summarized in **Table 4**. Please refer to **Fig. 1** when reading the following description of PLL circuit operation. MIX (3), a double balanced mixer, mixes the CAR output with the VFO output. MIX (2), which operates for the 18MHz band and above, mixes either 10 MHz, in the 14 and 18 MHz bands, or 20 MHz, in the 21, 24.5 and 28 MHz bands, with the output of MIX (3) to generate the appropriate frequency needed for each band, as shown in **Table 4**.

CIRCUIT DESCRIPTION

This is mixed with the VCO output for each band by MIX (1) to a frequency given in **Table 4**, which is then routed through LPF (1), amplified, and wave-shaped to a digital signal. A programmable divider divides this signal into a 500 kHz output. This programmable divider is preset, as shown in **Table 4**, by the BCD signal which is counter-generated from information coming from the band switch. The phase comparator used is a Motorola MC4044P. The loop filter is made of completely discrete components to minimize VCO spurious content.

Six VCOs cover all bands. If the PLL unlocks for any reason, it will be detected from the phase comparator output. This will turn off the VCO output to prevent spurious radiation and, at the same time, the display will be blanked to inform the operator of unlock status.

Q5 (TC5070P) is a presettable, 6-digit BCD counter which incorporates a 6-digit latch, 6-digit dynamic drive digital counter, and 7-segment decoder/driver. Band information supplied from the RF unit is applied to a diode matrix to preset the 100 kHz, 1 MHz and 10 MHz digits. Preset values are given in Fig. 3. For instance, to preset 14.000 MHz, with a 500 kHz counter input signal, the 10 MHz value is preset to 1, 1 MHz to 3, and 100 kHz to 5, and the 500 kHz

counter input signal is subtracted from 14.000 MHz. (If no counter input signal were present, 13.500 MHz would be displayed). Q5 supplies the display tube drivers with 7-segment information and dynamic drive control signals to light the fluorescent display tube.

In the counter unit, a diode matrix generates frequency division information and supplies the PLL unit with this information. If the PLL unlocks, a BLK (Blanking Low) signal will be applied to the digit driver IC (Q11) to blank the fluorescent display tube.

CIRCUIT DESCRIPTION

CAR OSCILLATOR

The CAR oscillator consists of a crystal controlled oscillator which uses two crystals : one for LSB and the other for USB and CW . Frequencies generated are shown in Fig. 1. The oscillating frequency can be varied by the IF SHIFT control during reception.

VFO

The VFO range is 5.5~6.0 MHz. Its oscillating frequency is automatically shifted 800 Hz up during CW transmission so that the actual operating frequency is always displayed.

CIRCUIT FEATURES

1. Optional filters available

The TS-530 is equipped with an 8.83 MHz IF filter with a bandwidth of 2.4 kHz. Narrow filters are separately available.

Installation of optional filters

One or two of the YK88SN, YK88C and YK88CN optional filters can be installed in the TS-530. Jumpers A and B (for filter switching) on the IF unit must be repositioned as shown in the following table.

CIRCUIT DESCRIPTION

2. IF SHIFT operation

The IF SHIFT circuit shifts the passband of the IF circuit without changing the receiving frequency. The relative position of the passband of the IF filter to the received signal is shifted when the IF SHIFT control is turned as shown in Fig. 7. The IF SHIFT circuit block diagram is shown in Fig. 8.

Fig. 7 IF SHIFT operation (for USB mode)

Frequencies within the PLL loop satisfy the following relationship.

$$N \cdot 500 \text{ kHz} = f_{\text{BPF1}} - f_{\text{VCO}} \quad (1)$$

where N : divisor of programmable divider

500 kHz : phase reference frequency

f_{BPF1} : input frequency to MIX (1)

f_{VCO} : VCO frequency

For example, in the case of 14 MHz reception, f_{BPF1} is given by eq. (1) as

$$f_{\text{BPF1}} = 10 \text{ MHz} + f_{\text{BPF2}} \quad (2)$$

where 10 MHz : band setting frequency

$$f_{\text{BPF2}} = f_{\text{VFO}} + f_{\text{CAR}} \quad (3)$$

where f_{VFO} : VFO frequency

f_{CAR} : carrier frequency

By substituting eq. (3) into eq.(2) and eq.(2) into eq.(1)

$$f_{\text{VCO}} = 10 \text{ MHz} + f_{\text{VFO}} + f_{\text{CAR}} - N \cdot 500 \text{ kHz}$$

$$\therefore f_{\text{CAR}} = f_{\text{VCO}} + (N \cdot 500 \text{ kHz} - 10 \text{ MHz} - f_{\text{VFO}})$$

Assuming that f_{VFO} is constant, when f_{CAR} is varied by $\pm \Delta f$,

$$\begin{aligned} f_{\text{CAR}} \pm \Delta f &= [f_{\text{VCO}} + (N \cdot 500 \text{ kHz} - 10 \text{ MHz} - f_{\text{VFO}})] \pm \Delta f \\ &= (f_{\text{VCO}} \pm \Delta f) + (N \cdot 500 \text{ kHz} - 10 \text{ MHz} - f_{\text{VFO}}) \end{aligned}$$

Thus, f_{VCO} varies by $\pm \Delta f$ as f_{CAR} is varied by $\pm \Delta f$.

The receiving frequency, f_{R} is given by

$$f_{\text{R}} = f_{\text{VCO}} - f_{\text{CAR}} \quad (4)$$

Therefore, when f_{CAR} is shifted by $+\Delta f$, receiving frequency f'_{R} is given by

$$\begin{aligned} f'_{\text{R}} &= (f_{\text{VCO}} + \Delta f) - (f_{\text{CAR}} + \Delta f) \\ &= f_{\text{VCO}} - f_{\text{CAR}} \end{aligned} \quad (5)$$

From equations (4) and (5),

$$f_{\text{R}} = f'_{\text{R}}$$

Thus the receiving frequency does not vary even if f_{CAR} is varied. However,

$$f_{\text{R}} = f_{\text{VCO}} - \text{IF frequency}$$

so the IF frequency varies as f_{VCO} varies.

This means that the relative position of the IF filter passband to the carrier position (of the received signal) is shifted by the same amount as the f_{VCO} variation.

CIRCUIT DESCRIPTION/AC VOLTAGE CONVERSION

3. Speech processor [Part of IF unit (X48-1310-00)]

This is an audio compression speech processor. When the processor switch is OFF, the audio signal amplified by Q11 (on the IF unit) passes through buffer amplifier Q12 (2SC1815Y) and is then applied to the MIC pot via diode switch D24 (1S1555).

When the processor switch is ON, the audio signal amplified by Q12 is applied to the AGC-type speech processor consisting of Q13 (μ PC1158H2), Q14 (2SC1815Y) and D26 (1N60). The speech processor effectively increases the "talk power" of the audio signal and feeds it to MIC pot via diode switch D25 (1S1555).

When the processor is ON, the ALC time constant is shortened by turning Q30 (2SK30A) in the AF unit OFF to heighten processor effect.

4. RIT/XIT operation

Conventional RIT function is provided by the RIT/XIT control. By also turning the XIT switch ON, the transmission frequency is shifted to the same frequency as received under RIT control.

TS-530(K) AC VOLTAGE CONVERSION

To operate the TS-530S (K) on 240V AC, the power transformer split primaries must be rewired from parallel to series connection.

1. Unplug the AC power cable.
2. Remove the bottom cover.
3. Remove the jumper wires between the two ϕ terminals and two 120 terminals on the bottom of the power transformer.
4. Connect the adjacent 120 and ϕ terminals at the middle of the transformer. This will provide 240V AC operation. For 220V AC operation, change the wires from 120 to 100 winding.
5. Change the AC fuse from 6A to 4A. Tag the power cord at the back of the radio to indicate that the transformer is strapped for 240V AC, and the power fuse should be 4A, and not 6A.
6. Replace the bottom cover and reconnect power to verify your work.

PARTS LIST

Note 1:

K: U.S.A. T: Britain W: Europe X: Australia

Note 2:

Only special type of resistors (example: cement, metal film, etc.) and capacitors (example: electrolytic, tantalum, mylar, temp. coeff. capacitors) are detailed in the PARTS LIST. For the value of all common type components, refer to the schematic diagram of the P.C. board illustration. Resistors not otherwise detailed are carbon type (1/4W or 1/8W). Order carbon resistors and capacitors according to the following example:

A carbon resistor's part number is RD14BY 2E222J.

A ceramic capacitor's number is CK45F1H103Z, CC45TH1H220J.

RECEIVER SECTION

- NOTES:**
- The figures shown are signal generator output required for a constant audio output with a constant AF gain control setting. Set the AF gain control for 0.63V/8Ω (50 mW) audio output 0 dBμ signal generator input at 14.175 MHz.
 - To inject signal generator output connect a 0.04μF 50V capacitor between the signal generator and the check point.

TRANSMITTER SECTION

- NOTES:**
- Levels are measured at 14.175 MHz in the CW MODE and SG SW OFF. Carrier level is adjusted until the meter indicates the maximum on-scale ALC reading.
 - All voltage measurements are read from an RF VTVM.
 - A probe with a capacitance of less than 3PF should be used and the ground should be made near the point of measurement.
